Code and figures for 'DTAT should supersede MTD' v1

David C. Norris david@precisionmethods.guru

March 2023

The following code reproduces all analyses and figures presented in article 'Dose Titration Algorithm Tuning (DTAT) should supersede the Maximum Tolerated Dose (MTD) concept in oncology dose-finding trials' (v1) submitted to F1000Research. Several analyses and figures excluded from the article are included here; numbering of figures does not necessarily correspond to that in the article.

Pharmacokinetic model

The simulations presented in the article are based on a notional cytotoxic drug, modeled after docetaxel. The pharmacokinetics are supposed to follow a standard 2-compartment pharmacokinetic model with central and peripheral compartments having volumes V_c and V_p , respectively, and drug concentrations $C_c(t)$ and $C_p(t)$. Denoting the intercompartmental and peripheral-compartment clearances Q and CL, respectively, and (time-dependent) cumulative dose by D(t), this model is a system of two ordinary differential equations (ODEs):

$$\dot{C}_c = \frac{\dot{D}}{V_c} - \frac{\mathrm{CL}}{V_c} C_c - \frac{\mathrm{Q}}{V_c} (C_c - C_p) \tag{1}$$

$$\dot{C}_p = \frac{\mathbf{Q}}{\mathbf{V_p}} (C_c - C_p). \tag{2}$$

Myelosuppression model

Chemotherapy-induced neutropenia (CIN) is supposed to occur according to the semimechanistic model of Friberg *et al.* (2002). The model may be expressed by the following system of ODEs:

$$\dot{Prol} = k_{tr} \cdot Prol \cdot (1 - E_{drug}) \left(\frac{Circ_0}{Circ} \right)^{\gamma} - k_{tr} \cdot Prol$$
 (3)

$$\dot{Tx_1} = k_{tr} \left(Prol - Tx_1 \right) \tag{4}$$

$$\dot{Tx}_2 = k_{tr} (Tx_1 - Tx_2) \tag{5}$$

$$\dot{Tx}_3 = k_{tr}(Tx_2 - Tx_3)$$
 (6)

$$\dot{Circ} = k_{tr} (Tx_3 - Circ) \tag{7}$$

Simulated population (inter-individual heterogeneity)

A population of 25 individuals is simulated, using population pharmacokinetic parameters reported for docetaxel in Onoue *et al.* (2016) and parameters estimated in Friberg *et al.* (2002) for their myelosuppression model.

PK/PD simulation model

To simulate the pharmacokinetics and (myelosuppressive) pharmacodynamics of our notional cytotoxic drug, we define a **pomp** model as follows:

```
pkpd.skel <- "
  double c2p = Q*(Cc - Cp); // central-to-peripheral flux
  DCc = (dose/duration)*(t < duration ? 1.0 : 0.0)/Vc - (CL/Vc)*Cc - c2p/Vc;
  DCp = c2p/Vp;
  // Myelosuppression model (Emax model, then dynamics per eqs 3-7 from Friberg et al 2002
  double Edrug = Emax*Cc/(Cc + EC50); // classic 'Emax model'
  DProl = (1-Edrug) * Prol * kTR * pow((Circ0 / Circ), gamma) - kTR * Prol;
  DTx_1 = kTR * (Prol - Tx_1);
 DTx_2 = kTR * (Tx_1 - Tx_2);
 DTx_3 = kTR * (Tx_2 - Tx_3);
 DCirc = kTR * (Tx_3 - Circ);
pkpd.txform <- "
  T_Circ0 = log(Circ0);
 T_kTR = log(kTR);
 T \to max = log(Emax);
 T_EC50 = log(EC50);
 T_CL = log(CL);
 T_Q = log(Q);
 T_Vc = log(Vc);
 T_Vp = log(Vp);
 T_sigma = log(sigma);
 T_dose = log(dose);
  T_duration = log(duration);
pkpd.txback <- "
  Circ0 = exp(T_Circ0);
 kTR = exp(T kTR);
 Emax = exp(T Emax);
 EC50 = exp(T_EC50);
  CL = exp(T CL);
  Q = \exp(T_Q);
  Vc = exp(T_Vc);
 Vp = exp(T_Vp);
  sigma = exp(T_sigma);
 dose = exp(T_dose);
  duration = exp(T_duration);
Tmax <- 21*24 # solve for full 21 days of 3-week cycle
df <- data.frame(time=c(seq(0.0, 1.95, 0.05) # q3min for 2h,
                        ,seq(2.0, Tmax, 1.0)) # then hourly until Tmax
                ,y=NA)
pkpd <- pomp(data = df
            , times="time", t0=0
            , skeleton=vectorfield(Csnippet(pkpd.skel))
            , statenames=c("Cc", "Cp", "Prol", "Tx.1", "Tx.2", "Tx.3", "Circ")
            , paramnames=c("Circ0", "kTR", "gamma", "Emax", "EC50", "CL", "Q", "Vc", "Vp"
                           ,"sigma","dose","duration"
                           ,"Cc.0","Cp.0","Prol.0","Tx.1.0","Tx.2.0","Tx.3.0","Circ.0")
```

```
, partrans=parameter_trans(
          toEst = Csnippet(pkpd.txform)
          ,fromEst = Csnippet(pkpd.txback)
)
```

In each subject, we now infuse the same initial dose over 1 hour, and integrate the PK and myelosuppression ODEs to obtain time series for plotting:

```
# initial conditions and output times
dose1 <- 100 # mg
Tinfusion <- 1 # 1-hour infusion
allout <- data.frame() # accumulator for nrow(pop) individual ODE solutions
parms <- function(id, dose, duration){</pre>
  parms <- unlist(pop[id,c('Circ0','kTR','gamma','Emax','EC50','CL','Q','Vc','Vp')])</pre>
  parms['sigma'] <- 0.05</pre>
  parms['dose'] <- dose</pre>
  parms['duration'] <- duration</pre>
  parms['Cc.0'] <- parms$Cp.0 <- 0.0
 parms[c('Prol.0','Tx.1.0','Tx.2.0','Tx.3.0','Circ.0')] <- parms$Circ0
}
for (id in 1:nrow(pop)) {
 Circ0 <- pop$Circ0[id]</pre>
  out <- trajectory(pkpd,
                     params=c(pop[pop$id==id, -which(names(pop) %in% c('id','MTT'))]
                               , sigma=0.05
                               , dose=dose1
                               , duration=Tinfusion
                               , Cc.0 = 0.0
                               , Cp.0 = 0.0
                               , Prol.0 = Circ0
                               , Tx.1.0 = Circ0
                               , Tx.2.0 = Circ0
                               , Tx.3.0 = Circ0
                               , Circ.0 = Circ0)) |> as.data.frame()

      ,print=FALSE
```

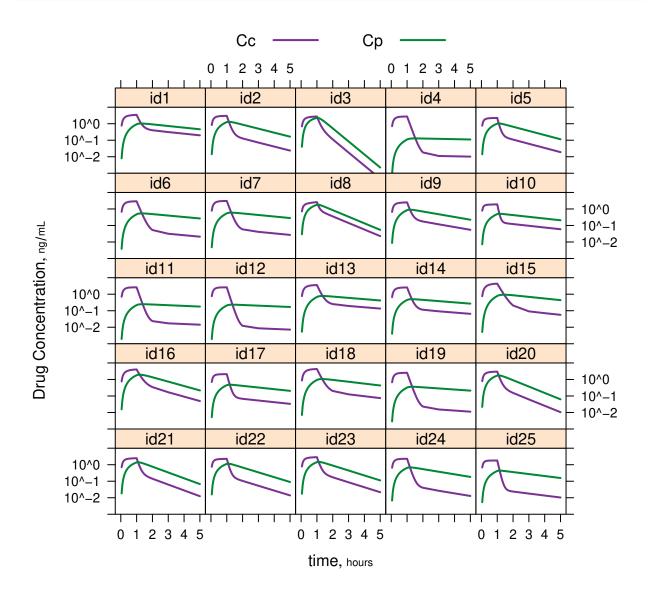

Figure 1: Two-compartment pharmacokinetics of the drug.

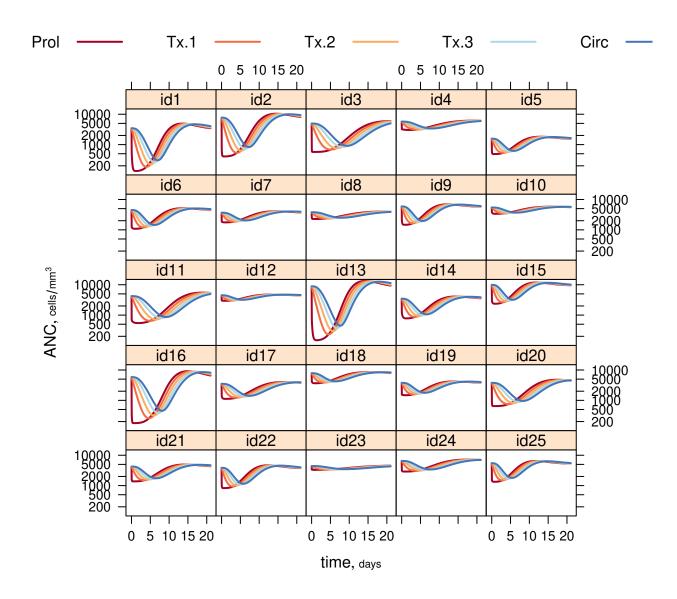

Figure 2: Myelosuppression in the 5-compartment model of Friberg *et al.*, with an infused dose of 100 mg. **Prol:** proliferative compartment; **Tx.n:** transit compartments; **Circ:** circulating cells.

Adaptive dosing based on a simple Newton-Raphson heuristic

The doChemo function defined below implements multiple, 3-week courses of chemotherapy with optional adaptive dosing based on the heuristic of Newton-Raphson root-finding. When adapt.dosing==FALSE, the infusion doses are stepped from 50 up to 500 mg, in increments that are evenly spaced on the scale of $\sqrt[4]{dose}$.

```
scaled <- function(dose, a=4.0) dose^(1/a)
dose.scale <- list(lim=scaled(c(40,550))</pre>
                                          , at=scaled(c(50, 100, 250, 500))

Linearize dynamics

We now demonstrate graphically an approximate linearization of ANC nadir level and timing, under logarithmic transformation of ANC and fourth-root transformation of dose.

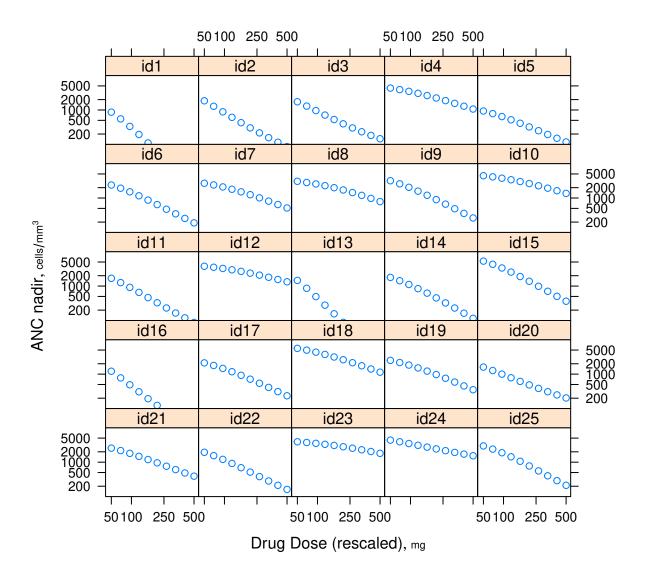

Figure 3: ANC nadir vs cytotoxic dose. Note the dose axis is scaled to achieve near-linearity.

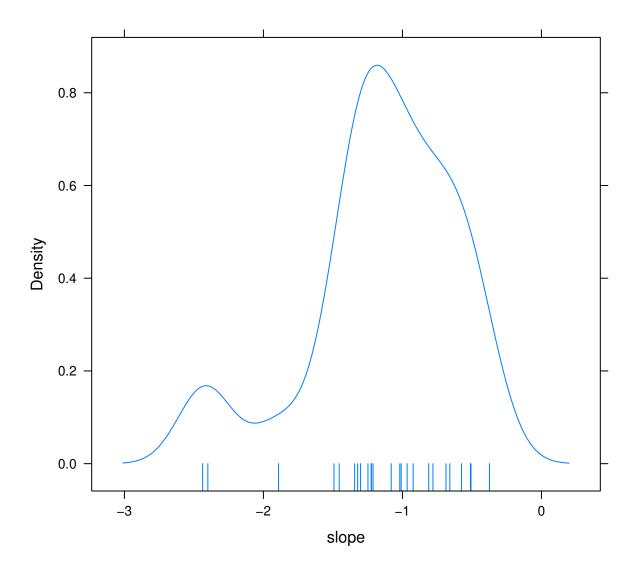

Figure 4: Slopes of $\log(ANC_{nadir})$ vs $\sqrt[4]{dose}$ for 25 simulated study subjects.

```
xYplot(time.nadir ~ scaled.dose | id, data=course, as.table=TRUE
    , layout=c(5,5)
    , scales=list(x=dose.scale)
)
```

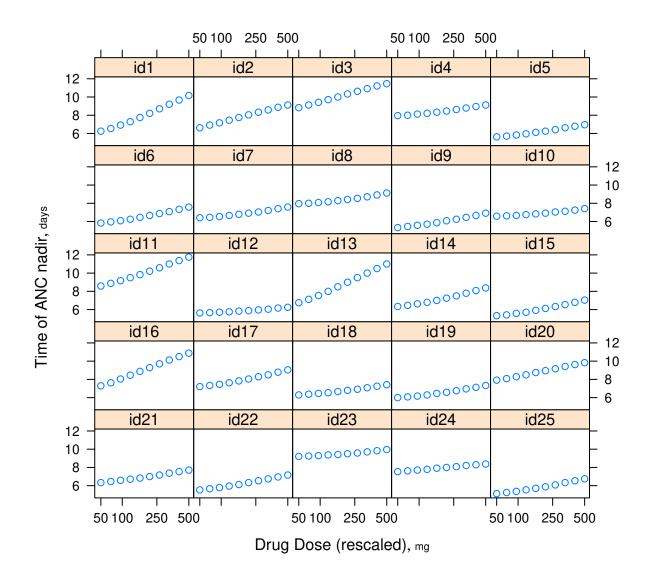

Figure 5: Timing of ANC nadir vs initial cytotoxic dose. Note the dose axis is scaled to achieve near-linearity.

```
##, subset=(dose %in% c(500,1000,1500,2500,4000))
xYplot(ANC.nadir ~ time.nadir | id, group=dose, data=course
    , as.table=TRUE
    , layout=c(5,5)
    , auto.key=list(columns=5, title="Dose (mg)", lines=FALSE)
    , par.settings=list(superpose.symbol=list(col=gray.colors(10, start=0.7, end=0.0)))
    , scales=list(y=list(log=TRUE, lim=c(10,6000), equispaced.log=FALSE))
    )
```

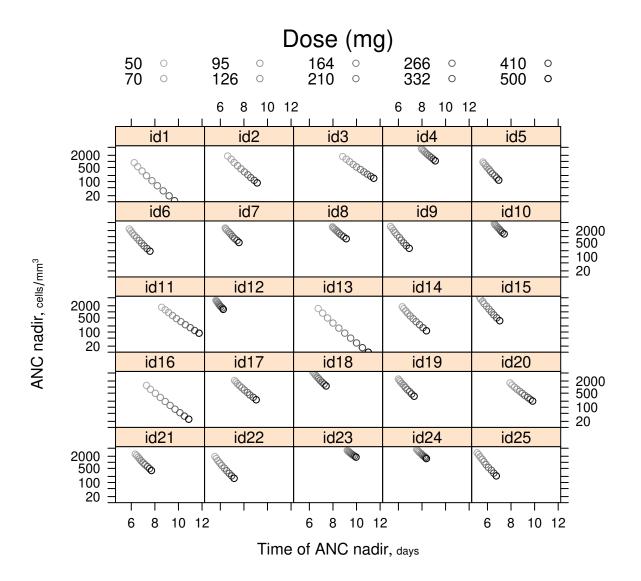

Figure 6: Timing and level of ANC nadir vs initial cytotoxic dose. The doses are equally spaced on a power-law scale that yields a roughly linear parametrization of the nadir coordinate paths.

Would day-7 ANC suffice as a proxy for nadir?

Evidently not; see Figure 7. Thus, CIN monitoring constitutes a nontrivial aspect of any practical implementation of DTAT, and requires explicit modeling in follow-on work. No doubt, the implementation must take the form of an adaptive process designed to balance (a) the burden of multiple blood draws against (b) the need for early warning of an impending severely neutropenic nadir that would indicate prophylactic administration of colony-stimulating factor.

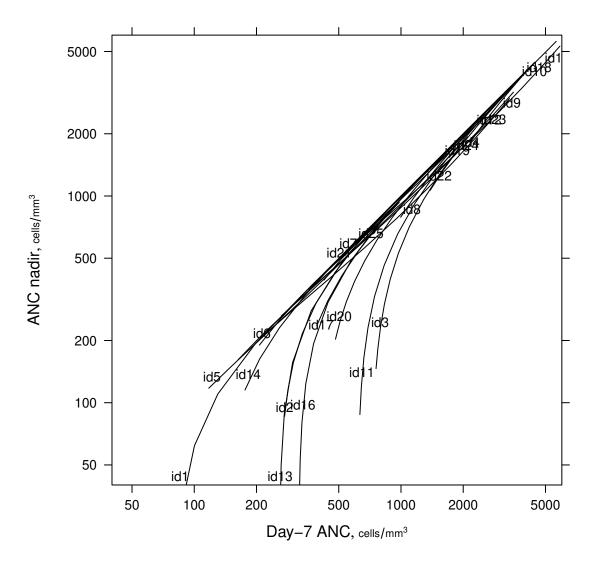

Figure 7: Day-7 ANC does not serve as suitable proxy for ANC nadir across the whole modeled population. Note that for some individuals (e.g., id3, id11, id20), the day-7 ANC may dangerously underestimate the actual nadir.
